

# application NOTE

## Using Sedona 1.2 Components from Tridium's Kits

### Introduction

This application note assists in the understanding of the Sedona components provided in Tridium's Sedona-1.2.28 release. Some of the Sedona components were changed or added since the previous release. New with the 1.2 release is that the Sedona components, previously concentrated in one Control kit, are now organized in smaller kits under a functional name. Components discussed in this document can be found in the following kits:

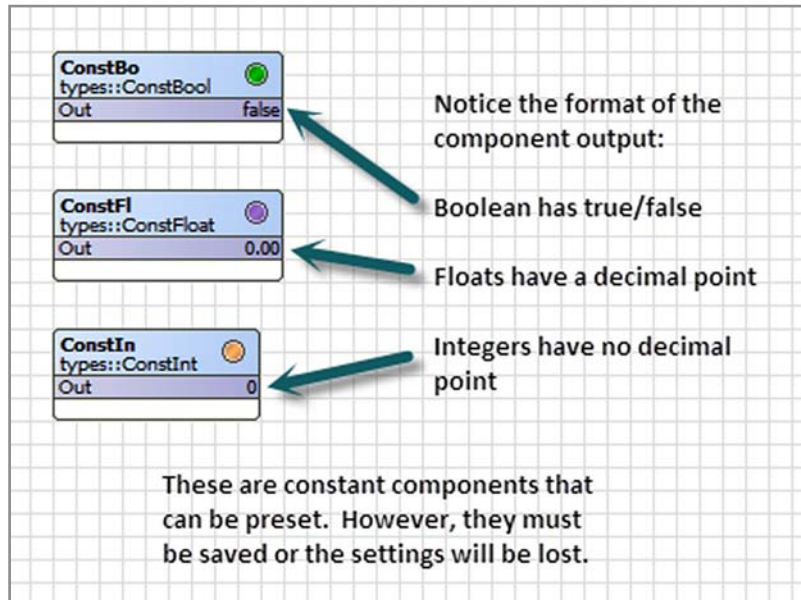

- basicSchedule
- datetimeSTD
- func
- hvac
- logic
- math
- pricomp
- timing
- types

The intent of this document is to explain the potential use of those components supplied by Tridium in their Sedona 1.2 release. All are included in Contemporary Controls' BASremote and BAScontrol product families. They have not been modified for use in these products. Contemporary Controls has product specific Sedona kits that address the uniqueness of the IO structure in the BASremote and BAScontrol products. These kits are not mentioned in this document. It is Contemporary Controls' policy to provide all Sedona kits to the Sedona Framework community without charge or license. This includes kits obtained from Tridium, kits with modified Tridium components, kits developed solely by Contemporary Controls to improve the control options available to systems integrators, and kits specific to Contemporary Controls' hardware. Any feedback is welcomed.

## Application Note — Using Sedona 1.2 Components

### Variable Types

Although there are several variable types used by Sedona, three are the most interesting — Boolean, Float and Integer. You can define constants for each type and use converting components to change the data representation to a different type.

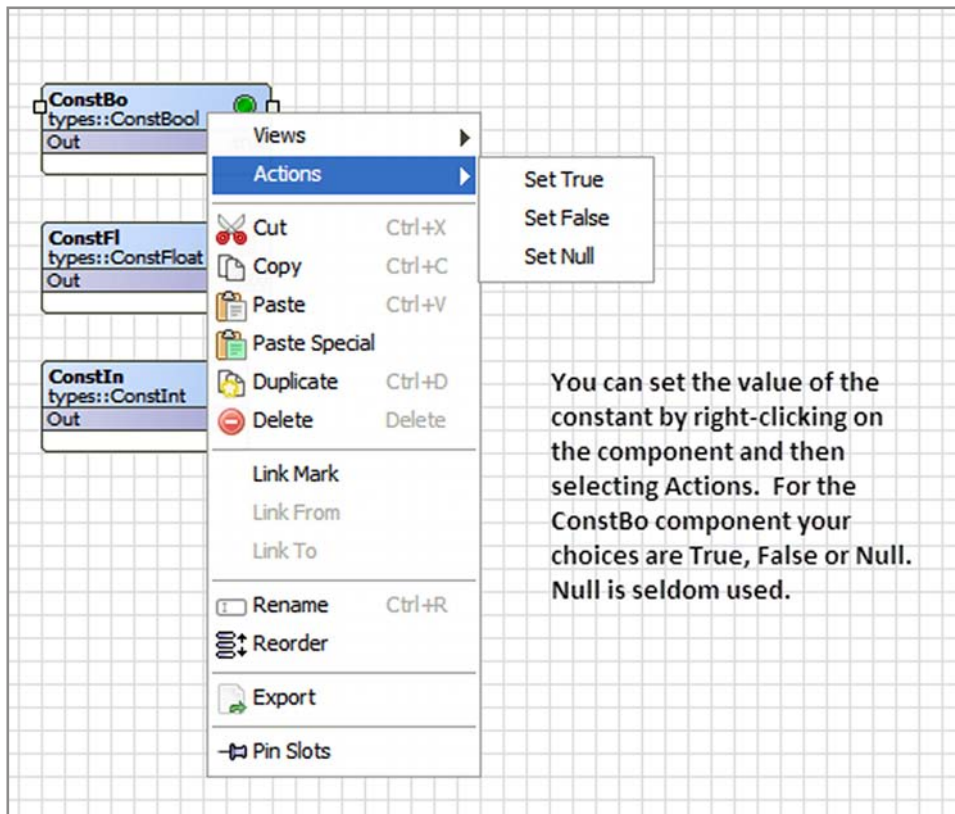

Notice the format of the component output:

- Boolean has true/false
- Floats have a decimal point
- Integers have no decimal point

These are constant components that can be preset. However, they must be saved or the settings will be lost.

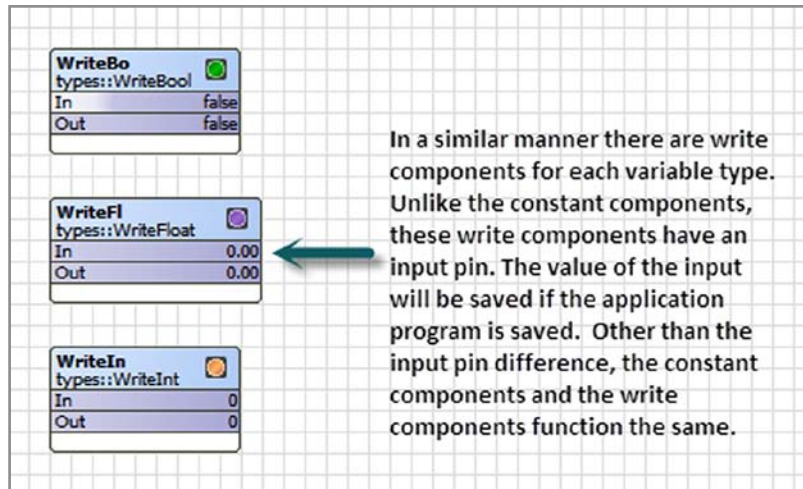

### Configuring Constants

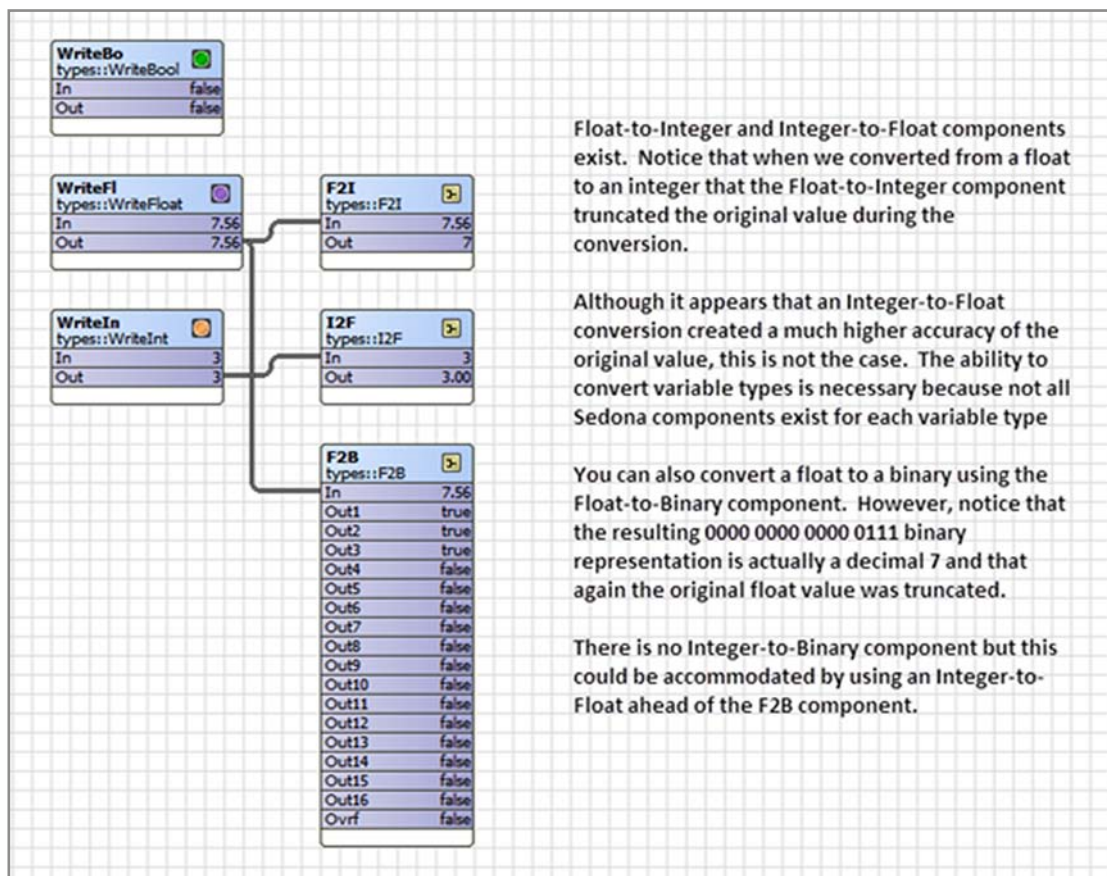

You can set the value of the constant by right-clicking on the component and then selecting Actions. For the ConstBo component your choices are True, False or Null. Null is seldom used.

### Comparing Two Floats

The comparator component (Cmpr) compares the the X input to that of the Y input. If X is less than Y, then the Xly output is true. If X equals Y then Xgy is true. If X is greater than Y then Xgy is true. Both inputs are floats and the outputs are Booleans. In this example the output of the Ramp is compared to that of a constant. Using the default values of the Ramp, the input X varies as a triangle between 0 and 100 every 10 seconds. You can watch how the comparator outputs change over this range.

### A Simple Clock — the TickToc

The TickToc component provides a convenient clock from 1 to 10 pulses per second. However, because of the controller scan time and other processing overhead it is recommended to use its default value of one second. More accurate timing is available from a real-time clock.

The Freq component can provide output values in pulses-per-second (Pps) or pulses-per-minute (Ppm). Because of the low-speed nature of these two components, the Ppm calculation will probably be the most useful.

# Application Note — Using Sedona 1.2 Components

## Introducing Counters

The diagram illustrates the configuration of two counter components. On the left, several components are connected to the inputs of the 'Count' and 'UpDn' components on the right.

- Count Component:** func::Count. Out: 33. In: true. Enable: true. R: false.
- UpDn Component:** func::UpDn. Out: 33.00. Ovr: false. In: true. Rst: false. C Dwn: false. Limit: 100.00. Hold At Limit: true.

Connections:

- TickToc (Out: true) connects to Count (In).
- ConstBo (Out: true) connects to Count (Enable).
- ConstB1 (Out: false) connects to UpDn (In).
- ConstB2 (Out: false) connects to UpDn (C Dwn).
- ConstF1 (Out: 100.00) connects to UpDn (Limit).
- ConstB3 (Out: true) connects to Count (R).

There are two counters. Count is an up/down counter with an integer output. It must be enabled to count. It can be reset to zero or preset to a positive value as long as the Enable pin is true. The direction pin (Dir) can be connected for programmable up/down counting.

UpDn is an up/down counter with a programmable direction input (C Dwn) which can also be configured. Although counters are inherently integer devices, the output of this component is a float. In this example a limit of 100 has been programmed. Once the limit is hit the overflow bit (Ovr) will be set. If Hold At Limit is true, the counter will not go past 100. If it is false, the counter will continue to count past the limit but the overflow bit will remain set. Resetting the counter returns the component to the start position while clearing the counter and overflow bit.

## Operating on Real-World Signals — Hysteresis and Limiting

The diagram illustrates the configuration of three signal processing components. On the left, components are connected to the inputs of the 'Hystere' and 'Limiter' components on the right.

- Ramp Component:** func::Ramp. Out: 65.15.
- Hystere Component:** func::Hysteresis. In: 64.91. Out: true. Rising Edge: 60.00. Falling Edge: 40.00.
- Limiter Component:** func::Limiter. Out: 60.00. In: 64.91. Low Lmt: 40.00. High Lmt: 60.00.

Connections:

- ConstF1 (40.00) connects to Ramp (In).
- ConstF1 (60.00) connects to Ramp (In).
- Ramp (Out: 65.15) connects to Hystere (In).
- ConstF1 (40.00) connects to Hystere (Falling Edge).
- Hystere (Out: 64.91) connects to Limiter (In).
- ConstF1 (60.00) connects to Limiter (High Lmt).

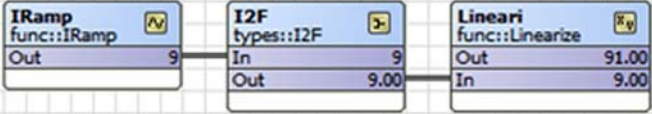

The hysteresis component (Hystere) has separate rising-edge and falling-edge trip points when setting a trigger on a float variable. It is ideal for creating a digital event from a real-world analog input. Its output is Boolean.

The Limiter component restricts the range of a float variable by outputting a float that does not exceed the configurable low-limit (Low Lmt) or high-limit (High Lmt). The Limiter only limits the range of its output and does not scale the input float.

# Application Note — Using Sedona 1.2 Components

## Handling Non-Linear Signals

The linearize component (Linearize) operates on a float input and creates a piece-wise linear representation of a non-linear input (such as a thermistor) or it can create a non-linear piece-wise representation of a linear input. There is complete flexibility in defining the ten X,Y coordinates along the output curve. The component determines the approximate output between the ten coordinates using linear interpolation.

<input type="checkbox"/> <input checked="" type="radio"/> Meta	Group [1] >>	
<input type="checkbox"/> <input checked="" type="radio"/> Out	<input type="text" value="56.50"/>	
<input type="checkbox"/> <input checked="" type="radio"/> In	<input type="text" value="7.50"/>	
<input type="checkbox"/> <input checked="" type="radio"/> X0	<input type="text" value="0.00"/>	<p>In this example we will do the reverse of what is commonly done. We will use a linear input and create a non-linear output that approximates the equation <math>Y=X^2</math> over the range of X values from 0 to 9. We need to input corresponding values of Y that obey the desired equation. To make it easy we will use integer values but this is not a restriction. For example, the square of 4 is 16 and the square of 5 is 25. We enter the X values as an independent variable and then the Y value as the dependent variable. We need to be careful that the input does not exceed 9 in this example because we do not define a corresponding value for Y above 9.</p>
<input type="checkbox"/> <input checked="" type="radio"/> Y0	<input type="text" value="0.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> X1	<input type="text" value="1.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> Y1	<input type="text" value="1.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> X2	<input type="text" value="2.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> Y2	<input type="text" value="4.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> X3	<input type="text" value="3.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> Y3	<input type="text" value="9.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> X4	<input type="text" value="4.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> Y4	<input type="text" value="16.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> X5	<input type="text" value="5.00"/>	<p>You can test the interpolation by entering a value for X in the In slot assuming no link is connected to the linearize component. This is done here. Notice that the result is 56.50 for an input value of 7.5. The correct value would have been 56.25 which is very close.</p>
<input type="checkbox"/> <input checked="" type="radio"/> Y5	<input type="text" value="25.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> X6	<input type="text" value="6.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> Y6	<input type="text" value="36.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> X7	<input type="text" value="7.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> Y7	<input type="text" value="49.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> X8	<input type="text" value="8.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> Y8	<input type="text" value="64.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> X9	<input type="text" value="9.00"/>	
<input type="checkbox"/> <input checked="" type="radio"/> Y9	<input type="text" value="81.00"/>	

# Application Note — Using Sedona 1.2 Components

## Simple Set-Reset Flip Flop — Bi-Stable Multivibrator

On the rare condition that both S and R transition from false-to-true during the same logic scan, R will take precedence because its state is tested last in the logic and therefore the output will be false.

The SRLatch appears to be straightforward logic block. The output would become true if the set (S) pin is high and would go low if the reset (R) pin goes high. However, both the S and R pins are positive leading-edge sensitive. Regardless of their steady-state condition, the output (OUT) will only change on the false-to-true transition of either input. If this occurs on the S pin the output goes high and will remain high until the R pin does its transition.

## The Loop Component — Basic PID Controller

The LP or loop component is one of the most complex components. It can provide three modes of control P-proportional, I-integral, and D-derivative. In this example we will assume a temperature loop with a setpoint (Sp) of 72 degrees and a controlled variable (Cv) currently at 72.5 degrees which is the space temperature which we want to control.

**LP (func::LP)**

Meta Group [1] >>

Enable

Sp

Cv

Out

Kp  [0.000000 - +inf]

Ki  /min [0.000000 - +inf]

Kd  s [0.000000 - +inf]

Max

Min

Bias

Max Delta  [0.000000 - +inf]

Direct

Ex Time  ms [0 - max]

Enable must be configured true otherwise there is no control.

Kp is the proportional gain which defaults to 1. Notice that the error signal is Cv-Sp or 0.5. The error multiplied by the proportional gain of 1 yields an output of 0.50. If the Ki and Kd factors are used, their contributions are also multiplied by the proportional gain factor. Ki is the integral gain in units of resets per minute. It is multiplied by the error signal. Kd is the derivative gain in seconds and it is also multiplied by the error signal.

Min and Max are the limits of the output signal. They can be set to any value. Bias can offset the output regardless of the error. Max Delta sets the rate of change of the output within the output limits. This will slow the output swing.

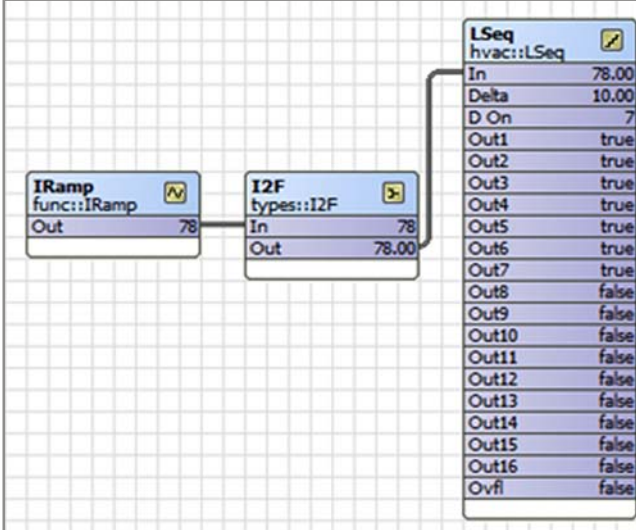

Bias only applies to proportional-only (P) control. When using a PI controller, reset-windup can be minimized by limiting the output range.

For a cooling application set Direct to true. For heating set it for false.

The loop equation is solved each execute time (Ex Time) in milliseconds.

# Application Note — Using Sedona 1.2 Components

## Linear Sequencer — Bar-Graph Representation of a Float

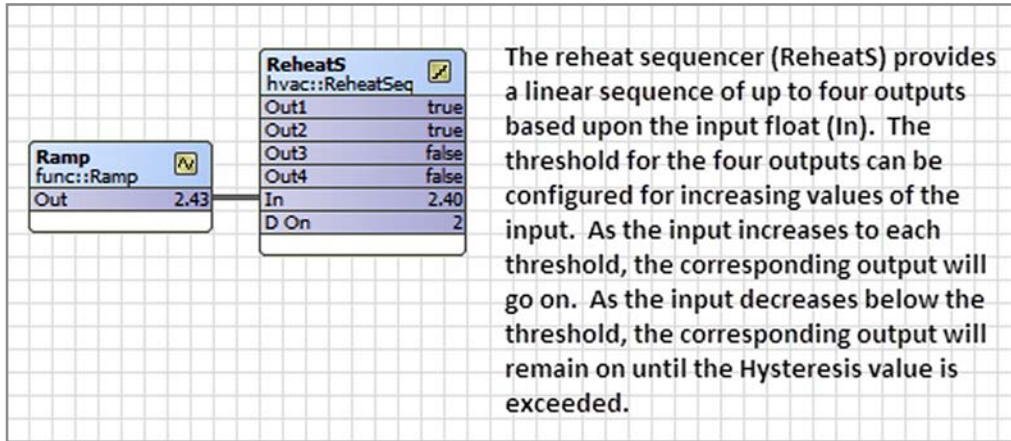

LSeq	
hvac::LSeq	
In	78.00
Delta	10.00
D On	7
Out1	true
Out2	true
Out3	true
Out4	true
Out5	true
Out6	true
Out7	true
Out8	false
Out9	false
Out10	false
Out11	false
Out12	false
Out13	false
Out14	false
Out15	false
Out16	false
Ovfl	false

The linear sequencer (LSeq) provides a digital representation of an input float similar in operation to a bar graph on audio equipment. It is easier to understand its operation using an integer input. There are 16 possible Boolean outputs plus one overflow (Ovfl) flag. The input ramp provides a triangle wave from 0 to 100. The sequencer was configured for a 0 minimum input and a 100 maximum input. The maximum number of outputs was configured for 9 yielding a Delta of 10.

<input type="checkbox"/> Meta	Group [1] >>	
<input type="checkbox"/> In	<input type="text" value="60.00"/>	
<input type="checkbox"/> In Min	<input type="text" value="0.00"/>	
<input type="checkbox"/> In Max	<input type="text" value="100.00"/>	
<input type="checkbox"/> Num Outs	<input type="text" value="9"/> [1 - 16]	The range of the linear sequencer is configured using In Min at the low-end and In Max at the high-end. Selecting the number of outputs (Num Outs) determines the difference (Delta) between successive outputs turning on. In this case the range is 100 and the number of desired outputs is 9. Divide 100 by Num Outs + 1 and you will get a Delta of 10.
<input type="checkbox"/> Delta	<input type="text" value="10.00"/>	
<input type="checkbox"/> D On	<input type="text" value="6"/> [0 - 255]	You will notice that the input (In) is at 60 and D On is indicating that six outputs are on. With an input between 0-9, there are no outputs on but once you hit a decade such as 10, 20 on up to 90, successive outputs will come on. At the maximum of 100, 9 lights will be on. If the input exceeds the maximum intended, the overflow flag will set but the number of outputs will remain as specified by Num Outs.
<input type="checkbox"/> Out1	<input checked="" type="checkbox"/> true	
<input type="checkbox"/> Out2	<input checked="" type="checkbox"/> true	
<input type="checkbox"/> Out3	<input checked="" type="checkbox"/> true	
<input type="checkbox"/> Out4	<input checked="" type="checkbox"/> true	
<input type="checkbox"/> Out5	<input checked="" type="checkbox"/> true	
<input type="checkbox"/> Out6	<input checked="" type="checkbox"/> true	
<input type="checkbox"/> Out7	<input type="checkbox"/> false	
<input type="checkbox"/> Out8	<input type="checkbox"/> false	
<input type="checkbox"/> Out9	<input type="checkbox"/> false	
<input type="checkbox"/> Out10	<input type="checkbox"/> false	
<input type="checkbox"/> Out11	<input type="checkbox"/> false	
<input type="checkbox"/> Out12	<input type="checkbox"/> false	
<input type="checkbox"/> Out13	<input type="checkbox"/> false	
<input type="checkbox"/> Out14	<input type="checkbox"/> false	
<input type="checkbox"/> Out15	<input type="checkbox"/> false	
<input type="checkbox"/> Out16	<input type="checkbox"/> false	
<input type="checkbox"/> Ovfl	<input type="checkbox"/> false	

## Application Note — Using Sedona 1.2 Components

### Reheat Sequencer — Four Staged Outputs from a Float Input

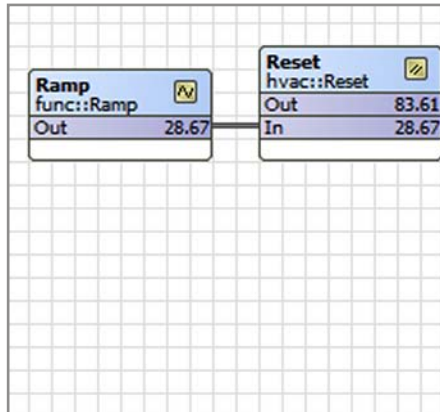

The reheat sequencer (ReheatS) provides a linear sequence of up to four outputs based upon the input float (In). The threshold for the four outputs can be configured for increasing values of the input. As the input increases to each threshold, the corresponding output will go on. As the input decreases below the threshold, the corresponding output will remain on until the Hysteresis value is exceeded.

ReheatS (hvac::ReheatSeq)		
<input type="checkbox"/> Meta	Group [1] >>	
<input type="checkbox"/> Out1	<input checked="" type="radio"/> true	Enable must to true otherwise the outputs to be false.
<input type="checkbox"/> Out2	<input checked="" type="radio"/> true	
<input type="checkbox"/> Out3	<input checked="" type="radio"/> true	
<input type="checkbox"/> Out4	<input type="radio"/> false	There are four possible threshold settings corresponding to four outputs. As the input signal increases to each threshold its corresponding output goes on and stays on until the input drops below the threshold plus the value of the hysteresis.
<input type="checkbox"/> In	<input type="text" value="2.93"/>	
<input type="checkbox"/> Enable	<input checked="" type="radio"/> true	
<input type="checkbox"/> D On	<input type="text" value="3"/> [0 - 255]	
<input type="checkbox"/> Hysteresis	<input type="text" value="0.25"/>	
<input type="checkbox"/> Threshold1	<input type="text" value="1.00"/>	The input signal is decreasing but it has not exceeded the amount of the threshold so output 3 (Out3) remains set. Once the signal is below 2.75, output 3 will go off.
<input type="checkbox"/> Threshold2	<input type="text" value="2.00"/>	
<input type="checkbox"/> Threshold3	<input type="text" value="3.00"/>	
<input type="checkbox"/> Threshold4	<input type="text" value="4.00"/>	

# Application Note — Using Sedona 1.2 Components

## Reset — Scaling a Float Input between Two Limits

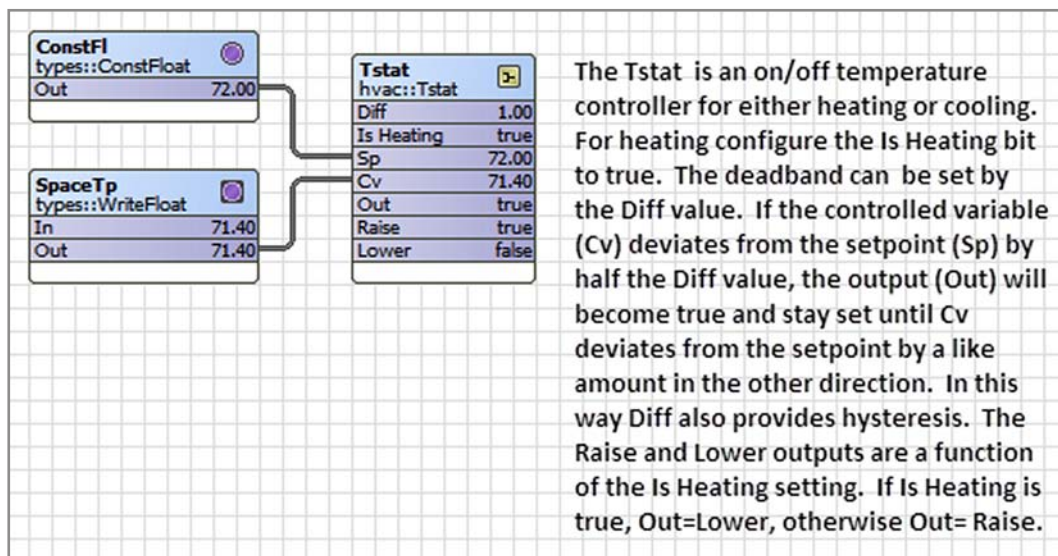

The reset component (Reset) will scale the output linearly between two limits. The input range must be configured by setting In Min and In Max. The corresponding output for those two points must be configured as Out Min and Out Max. If the input signal exceeds the defined input range, the output will be clamped to one of the two output limits.

Reset (hvac::Reset)	
<input type="checkbox"/> Meta	Group [1] >>
<input type="checkbox"/> Out	81.22
<input type="checkbox"/> In	27.34
<input type="checkbox"/> In Min	0.00
<input type="checkbox"/> In Max	100.00
<input type="checkbox"/> Out Min	32.00
<input type="checkbox"/> Out Max	212.00

In this example we are converting degrees Celsius to degrees Fahrenheit within the 0-100 degree Celsius range. Therefore we set Out Min and Out Max to the corresponding Fahrenheit values. All Celsius input values between these two limits will be interpolated thereby providing the correct Fahrenheit values.

## Tstat — Basic On/Off Temperature Controller

The Tstat is an on/off temperature controller for either heating or cooling. For heating configure the Is Heating bit to true. The deadband can be set by the Diff value. If the controlled variable (Cv) deviates from the setpoint (Sp) by half the Diff value, the output (Out) will become true and stay set until Cv deviates from the setpoint by a like amount in the other direction. In this way Diff also provides hysteresis. The Raise and Lower outputs are a function of the Is Heating setting. If Is Heating is true, Out=Lower, otherwise Out= Raise.

# Application Note — Using Sedona 1.2 Components

## Real-Time Clock and Scheduling

<b>DateTim</b> datetimeStd::DateTimeServiceStd	
Nanos	426634164000000000 ns
Hour	21
Minute	29
Second	24
Year	2013
Month	7
Day	8
Day Of Week	1

The DateTim component provides real-time information. There is no need to place it on the wiresheet. However, if you need specific information from the component for driving logic, you can connect to the various integer outputs such as Hour, Minute and Second.

<b>DailySc</b> basicSchedule::DailyScheduleBool	
Out	false

There are two schedule components which have different output types. One is for Boolean and the other for float. There is no need to connect the DateTim component to either of the schedulers. Each scheduler can handle two events over the 24 hour period by configuring the time and duration of each event. The output of each schedule will change with each event. If more events or more outputs are needed, multiple schedulers can be placed on the wiresheet.

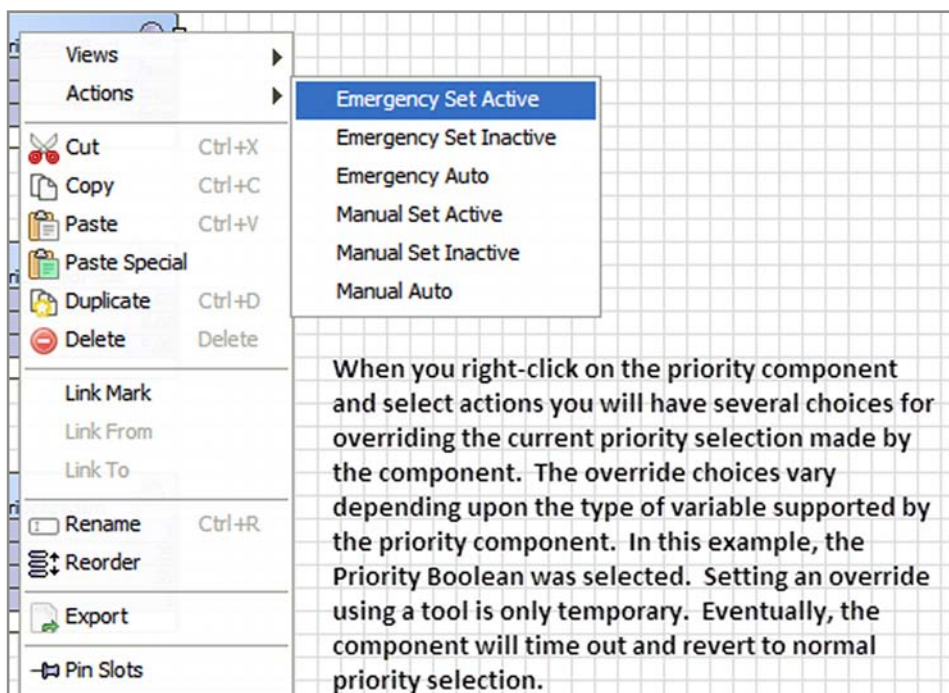

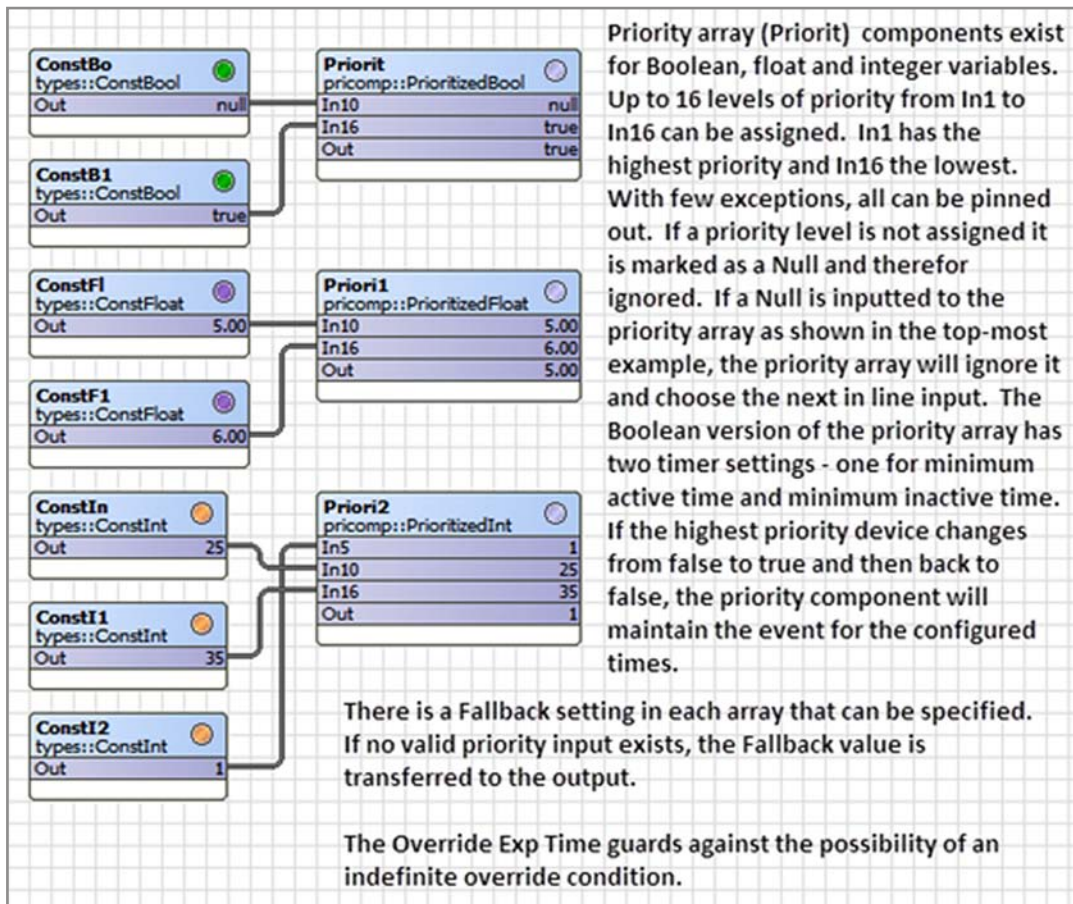

<b>DailyS1</b> basicSchedule::DailyScheduleFloat	
Out	0.00

<input checked="" type="radio"/> DailyS1 (basicSchedule::DailyScheduleFloat)	
<input type="checkbox"/> <input checked="" type="radio"/> Meta	Group [1] >>
<input type="checkbox"/> <input checked="" type="radio"/> Start1	12:00 AM
<input type="checkbox"/> <input checked="" type="radio"/> Dur1	00000h 00m [0ms - 1day]
<input type="checkbox"/> <input checked="" type="radio"/> Start2	12:00 AM
<input type="checkbox"/> <input checked="" type="radio"/> Dur2	00000h 00m [0ms - 1day]
<input type="checkbox"/> <input checked="" type="radio"/> Val1	0.00
<input type="checkbox"/> <input checked="" type="radio"/> Val2	0.00
<input type="checkbox"/> <input checked="" type="radio"/> Def Val	0.00
<input type="checkbox"/> <input checked="" type="radio"/> Out	0.00

Configuration of the two scheduler components is similar. For the float version, Val1 and Val2 need to be specified along with the start times (Start1 and Start2) and the durations (Dur1 and Dur2). The output (Out) will assert either Val1 or Val2 during the scheduled times. If neither are programmed, the Def Val should be configured.
